

Standup 8: Age Demographics Analysis

This week focused on analyzing age groups by categorizing borrowers into life stages. Middle-aged individuals demonstrated the strongest credit profiles, while younger and older groups showed higher proportions of poor scores. Chi-Square testing confirmed the relationship was statistically significant.

A challenge was choosing age group boundaries that were analytically meaningful without oversimplifying real-world complexity.

Next week, I will examine credit utilization patterns using ANOVA. Visual and statistical results are linked in the documentation.
